# Link Layer

### **Transportation analogy**

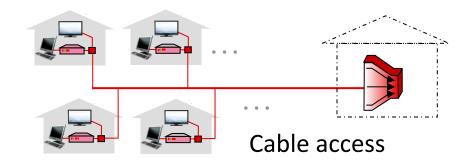

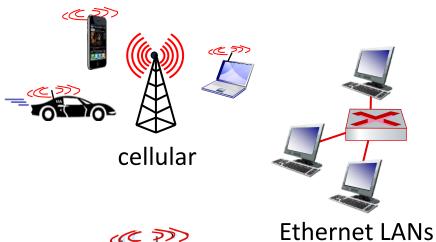

#### transportation analogy:

- trip from Princeton to Lausanne
  - limo: Princeton to JFK
  - plane: JFK to Geneva
  - train: Geneva to Lausanne
- tourist = datagram
- transport segment = communication link
- transportation mode = linklayer protocol
- travel agent = routing algorithm

## Link layer: services

- framing, link access:
  - encapsulate datagram into frame, adding header, trailer
  - channel access if shared medium
  - "MAC" addresses in frame headers identify source, destination (different from IP address!)
- reliable delivery between adjacent nodes
  - we already know how to do this!
  - seldom used on low bit-error links
  - wireless links: high error rates
    - Q: why both link-level and end-end reliability?

## Link layer: services (more)

#### • flow control:

pacing between adjacent sending and receiving nodes

#### error detection:

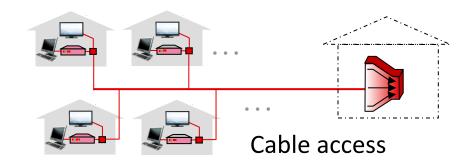

- errors caused by signal attenuation, noise.
- receiver detects errors, signals retransmission, or drops frame

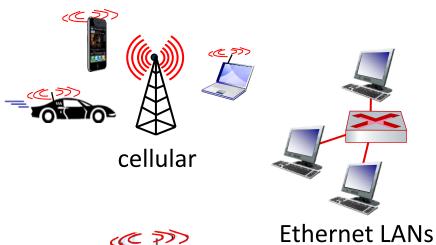

#### error correction:

receiver identifies and corrects bit error(s) without retransmission

### half-duplex and full-duplex:

 with half duplex, nodes at both ends of link can transmit, but not at same time

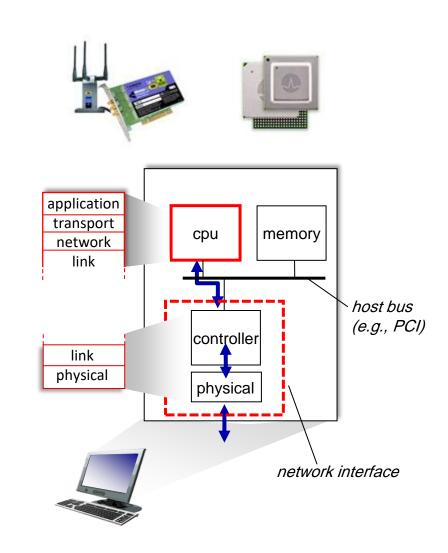

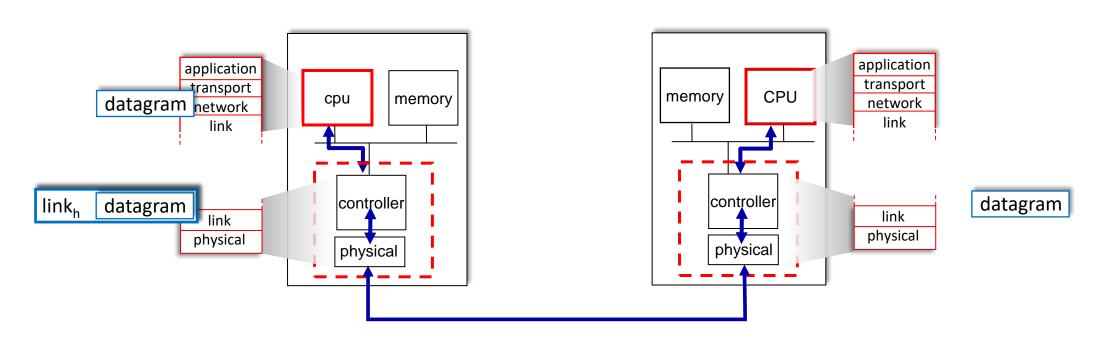

## Host link-layer implementation

- in each-and-every host
- link layer implemented on-chip or in network interface card (NIC)
  - implements link, physical layer
- attaches into host's system buses
- combination of hardware, software, firmware

## Interfaces communicating

#### sending side:

- encapsulates datagram in frame
- adds error checking bits, reliable data transfer, flow control, etc.

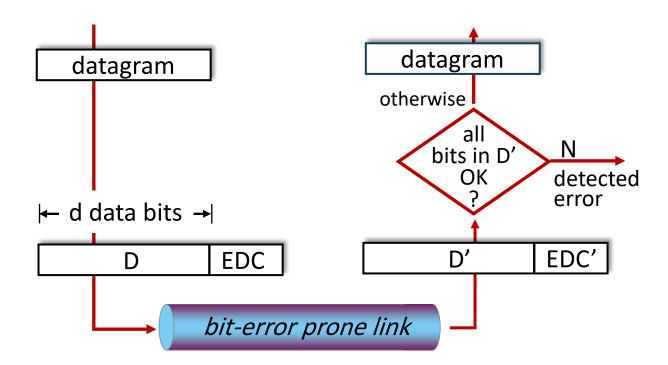

#### receiving side:

- looks for errors, reliable data transfer, flow control, etc.
- extracts datagram, passes to upper layer at receiving side

### **Error detection**

EDC: error detection and correction bits (e.g., redundancy)

D: data protected by error checking, may include header fields

Error detection not 100% reliable!

- protocol may miss some errors, but rarely
- larger EDC field yields better detection and correction

### Multiple access links, protocols

### two types of "links":

- point-to-point
  - point-to-point link between Ethernet switch, host
  - PPP for dial-up access
- broadcast (shared wire or medium)
  - old-school Ethernet
  - upstream HFC in cable-based access network
  - 802.11 wireless LAN, 4G/4G. satellite

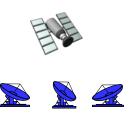

shared wire (e.g., cabled Ethernet)

shared radio: 4G/5G

shared radio: WiFi

shared radio: satellite

humans at a cocktail party (shared air, acoustical)

## Multiple access protocols

- single shared broadcast channel
- two or more simultaneous transmissions by nodes: interference
  - collision if node receives two or more signals at the same time

### multiple access protocol

- distributed algorithm that determines how nodes share channel,
  i.e., determine when node can transmit
- communication about channel sharing must use channel itself!
  - no out-of-band channel for coordination

## An ideal multiple access protocol

given: multiple access channel (MAC) of rate R bps desiderata:

- 1. when one node wants to transmit, it can send at rate R.
- 2. when M nodes want to transmit, each can send at average rate R/M
- 3. fully decentralized:
  - no special node to coordinate transmissions
  - no synchronization of clocks, slots
- 4. simple

## MAC protocols: taxonomy

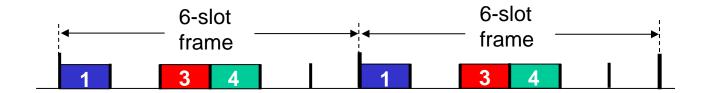

#### three broad classes:

- channel partitioning
  - divide channel into smaller "pieces" (time slots, frequency, code)
  - allocate piece to node for exclusive use
- random access
  - channel not divided, allow collisions
  - "recover" from collisions
- "taking turns"
  - nodes take turns, but nodes with more to send can take longer turns

### Channel partitioning MAC protocols: TDMA

#### TDMA: time division multiple access

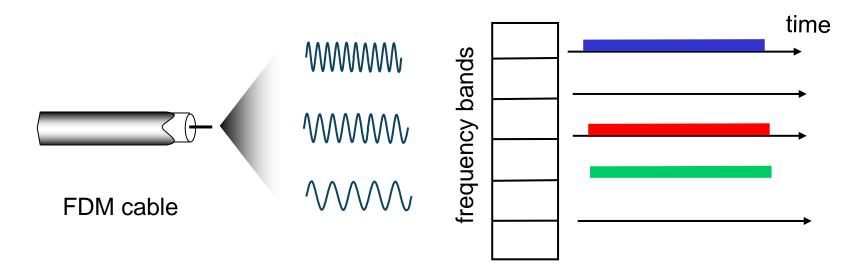

- access to channel in "rounds"
- each station gets fixed length slot (length = packet transmission time) in each round
- unused slots go idle
- example: 6-station LAN, 1,3,4 have packets to send, slots 2,5,6 idle

### Channel partitioning MAC protocols: FDMA

#### FDMA: frequency division multiple access

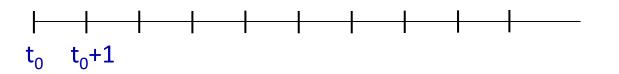

- channel spectrum divided into frequency bands
- each station assigned fixed frequency band
- unused transmission time in frequency bands go idle
- example: 6-station LAN, 1,3,4 have packet to send, frequency bands 2,5,6 idle

### Random access protocols

- when node has packet to send
  - transmit at full channel data rate R
  - no a priori coordination among nodes
- two or more transmitting nodes: "collision"
- random access protocol specifies:
  - how to detect collisions
  - how to recover from collisions (e.g., via delayed retransmissions)
- examples of random access MAC protocols:
  - ALOHA, slotted ALOHA
  - CSMA, CSMA/CD, CSMA/CA

### Slotted ALOHA

#### assumptions:

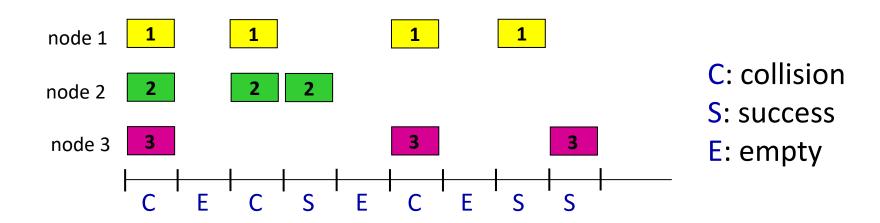

- all frames same size
- time divided into equal size slots (time to transmit 1 frame)
- nodes start to transmit only slot beginning
- nodes are synchronized
- if 2 or more nodes transmit in slot, all nodes detect collision

#### operation:

- when node obtains fresh frame, transmits in next slot
  - if no collision: node can send new frame in next slot
  - *if collision:* node retransmits frame in each subsequent slot with probability *p* until success

randomization – why?

### Slotted ALOHA

#### Pros:

- single active node can continuously transmit at full rate of channel
- highly decentralized: only slots in nodes need to be in sync
- simple

#### Cons:

- collisions, wasting slots
- idle slots
- nodes may be able to detect collision in less than time to transmit packet
- clock synchronization

## Slotted ALOHA: efficiency

efficiency: long-run fraction of successful slots (many nodes, all with many frames to send)

- *suppose: N* nodes with many frames to send, each transmits in slot with probability *p* 
  - prob that given node has success in a slot =  $p(1-p)^{N-1}$
  - prob that any node has a success =  $Np(1-p)^{N-1}$
  - max efficiency: find  $p^*$  that maximizes  $Np(1-p)^{N-1}$
  - for many nodes, take limit of  $Np^*(1-p^*)^{N-1}$  as N goes to infinity, gives:

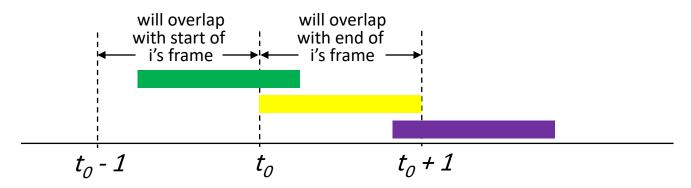

max efficiency = 1/e = .37

• at best: channel used for useful transmissions 37% of time!

### Pure ALOHA

- unslotted Aloha: simpler, no synchronization
  - when frame first arrives: transmit immediately
- collision probability increases with no synchronization:
  - frame sent at t<sub>0</sub> collides with other frames sent in [t<sub>0</sub>-1,t<sub>0</sub>+1]

pure Aloha efficiency: 18%!

## CSMA (carrier sense multiple access)

#### simple CSMA: listen before transmit:

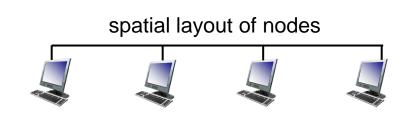

- if channel sensed idle: transmit entire frame
- if channel sensed busy: defer transmission
- human analogy: don't interrupt others!

### CSMA/CD: CSMA with collision detection

- collisions detected within short time
- colliding transmissions aborted, reducing channel wastage
- collision detection easy in wired, difficult with wireless
- human analogy: the polite conversationalist

### CSMA: collisions

- collisions can still occur with carrier sensing:
  - propagation delay means two nodes may not hear each other's juststarted transmission
- collision: entire packet transmission time wasted
  - distance & propagation delay play role in in determining collision probability

 $t_1$ 

### CSMA/CD:

- CSMA/CD reduces the amount of time wasted in collisions
  - transmission aborted on collision detection

### Ethernet CSMA/CD algorithm

- 1. Ethernet receives datagram from network layer, creates frame
- 2. If Ethernet senses channel:

if idle: start frame transmission.

if busy: wait until channel idle, then transmit

- 3. If entire frame transmitted without collision done!
- 4. If another transmission detected while sending: abort, send jam signal
- 5. After aborting, enter binary (exponential) backoff:
  - after mth collision, chooses K at random from  $\{0,1,2,...,2^m-1\}$ . Ethernet waits K 512 bit times, returns to Step 2
  - more collisions: longer backoff interval

## "Taking turns" MAC protocols

#### channel partitioning MAC protocols:

- share channel efficiently and fairly at high load
- inefficient at low load: delay in channel access, 1/N bandwidth allocated even if only 1 active node!

#### random access MAC protocols

- efficient at low load: single node can fully utilize channel
- high load: collision overhead

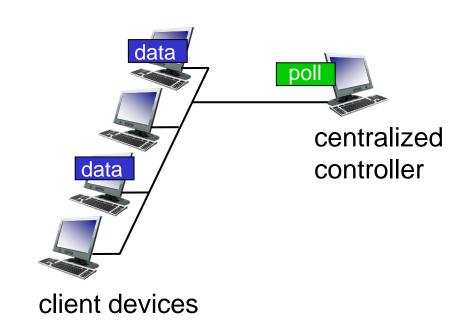

### "taking turns" protocols

look for best of both worlds!

## "Taking turns" MAC protocols

### polling:

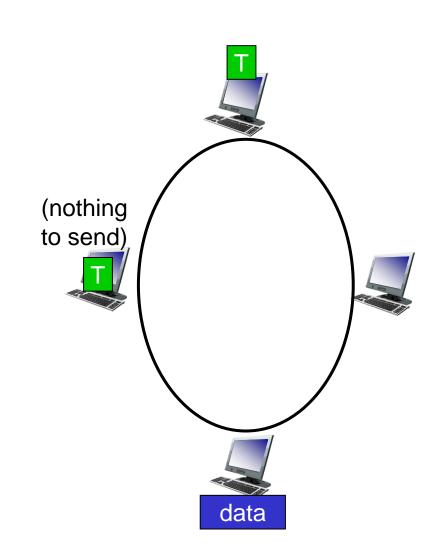

- centralized controller "invites" other nodes to transmit in turn
- typically used with "dumb" devices
- concerns:
  - polling overhead
  - latency
  - single point of failure (master)
- Bluetooth uses polling

### "Taking turns" MAC protocols

#### token passing:

- control token message explicitly passed from one node to next, sequentially
  - transmit while holding token
- concerns:
  - token overhead
  - latency
  - single point of failure (token)

### Summary of MAC protocols

- channel partitioning, by time, frequency or code
  - Time Division, Frequency Division
- random access (dynamic),
  - ALOHA, S-ALOHA, CSMA, CSMA/CD
  - carrier sensing: easy in some technologies (wire), hard in others (wireless)
  - CSMA/CD used in Ethernet
  - CSMA/CA used in 802.11
- taking turns
  - polling from central site, token passing
  - Bluetooth, FDDI, token ring

# **LANs**

#### MAC addresses

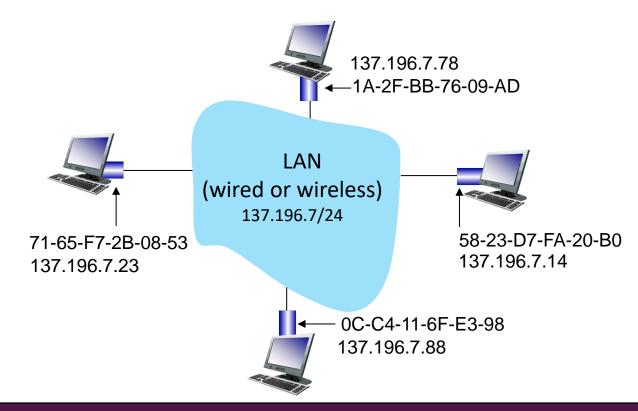

- 32-bit IP address:
  - network-layer address for interface
  - used for layer 3 (network layer) forwarding
  - e.g.: 128.119.40.136
- MAC (or LAN or physical or Ethernet) address:
  - function: used "locally" to get frame from one interface to another physically-connected interface (same subnet, in IP-addressing sense)
  - 48-bit MAC address (for most LANs) burned in NIC ROM, also sometimes software settable
  - e.g.: 1A-2F-BB-76-09-AD

hexadecimal (base 16) notation (each "numeral" represents 4 bits)

#### MAC addresses

#### each interface on LAN

- has unique 48-bit MAC address
- has a locally unique 32-bit IP address (as we've seen)

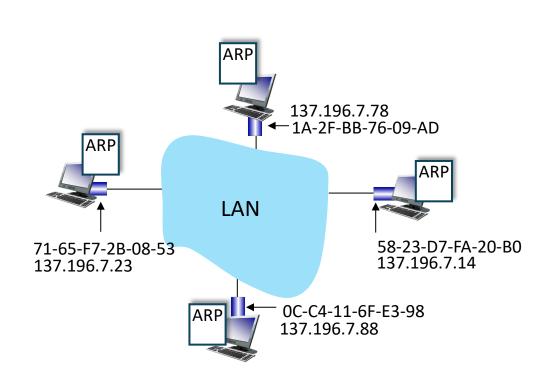

### MAC addresses

- MAC address allocation administered by IEEE
- manufacturer buys portion of MAC address space (to assure uniqueness)
- analogy:
  - MAC address: like Social Security Number
  - IP address: like postal address
- MAC flat address: portability
  - can move interface from one LAN to another
  - recall IP address not portable: depends on IP subnet to which node is attached

## ARP: address resolution protocol

Question: how to determine interface's MAC address, knowing its IP address?

ARP table: each IP node (host, router) on LAN has table

 IP/MAC address mappings for some LAN nodes:

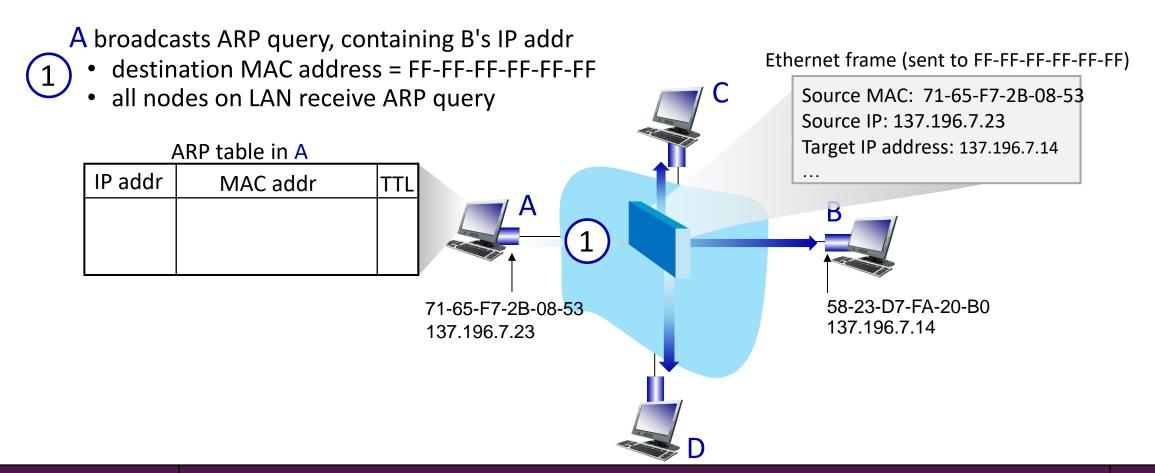

< IP address; MAC address; TTL>

 TTL (Time To Live): time after which address mapping will be forgotten (typically 20 min)

## ARP protocol in action

#### example: A wants to send datagram to B

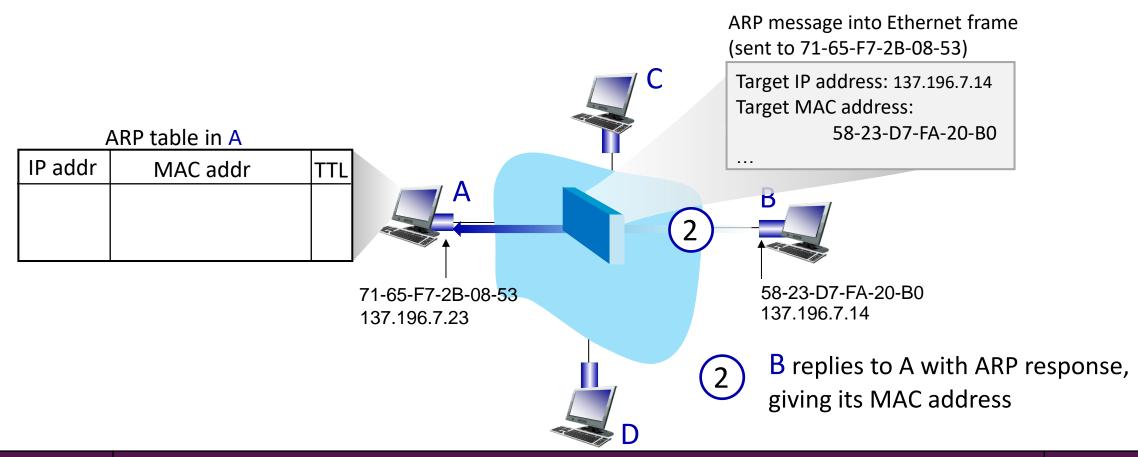

• B's MAC address not in A's ARP table, so A uses ARP to find B's MAC address

### ARP protocol in action

#### example: A wants to send datagram to B

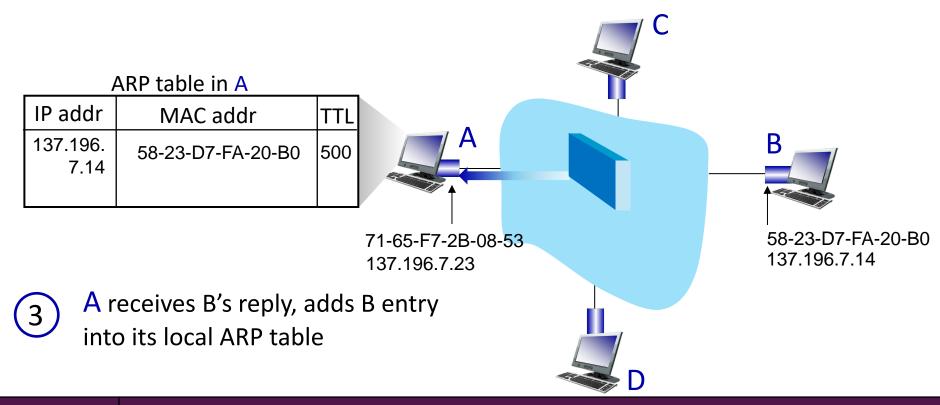

• B's MAC address not in A's ARP table, so A uses ARP to find B's MAC address

### ARP protocol in action

#### example: A wants to send datagram to B

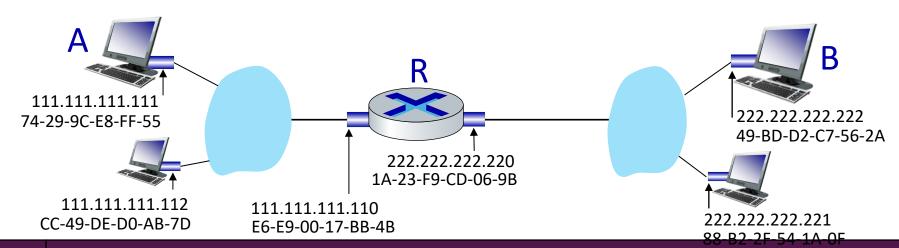

• B's MAC address not in A's ARP table, so A uses ARP to find B's MAC address

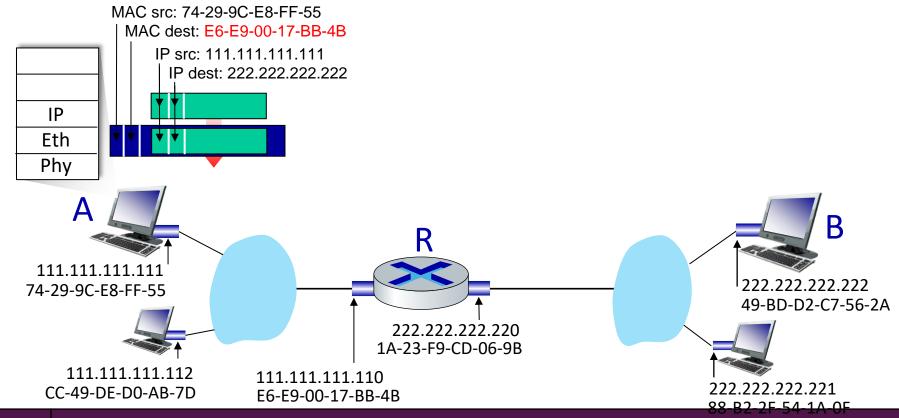

### Routing to another subnet: addressing

#### walkthrough: sending a datagram from A to B via R

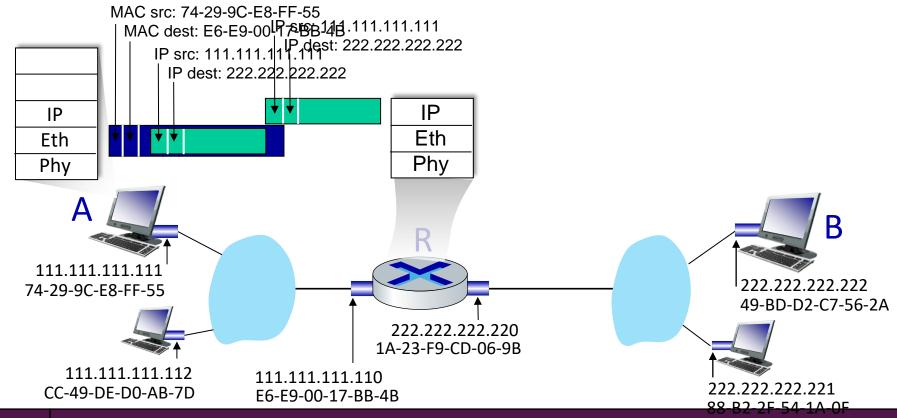

- focus on addressing at IP (datagram) and MAC layer (frame) levels
- assume that:
  - A knows B's IP address
  - A knows IP address of first hop router, R (how?)
  - A knows R's MAC address (how?)

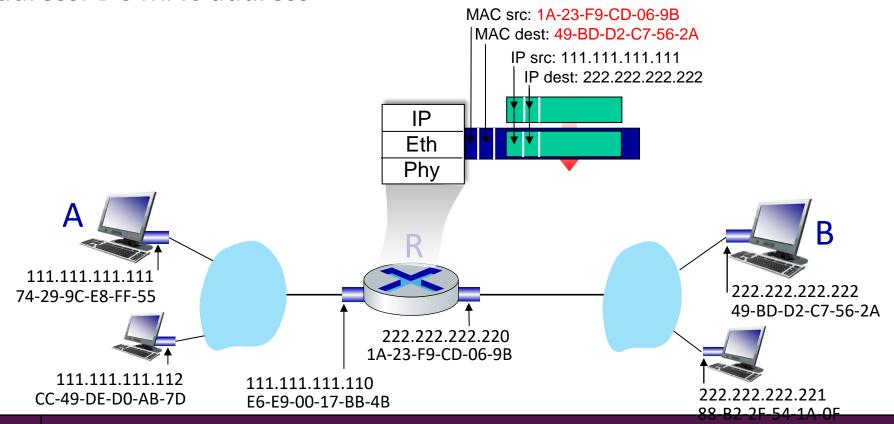

- A creates IP datagram with IP source A, destination B
- A creates link-layer frame containing A-to-B IP datagram
  - R's MAC address is frame's destination

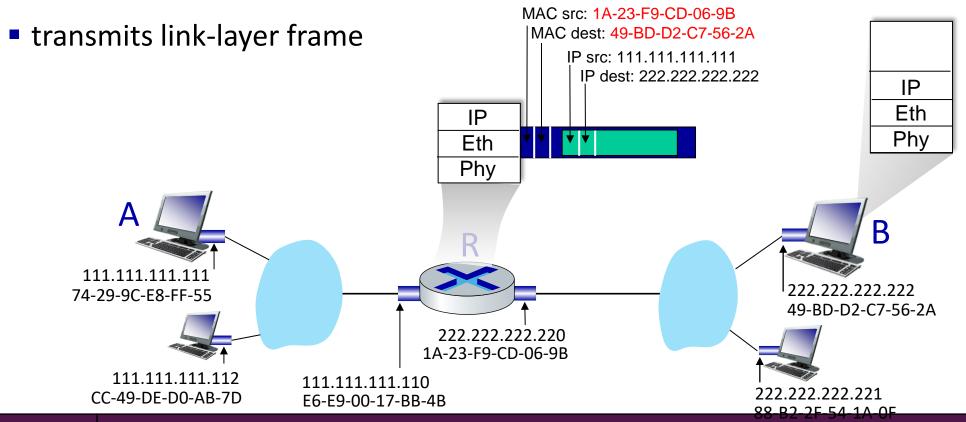

- frame sent from A to R
- frame received at R, datagram removed, passed up to IP

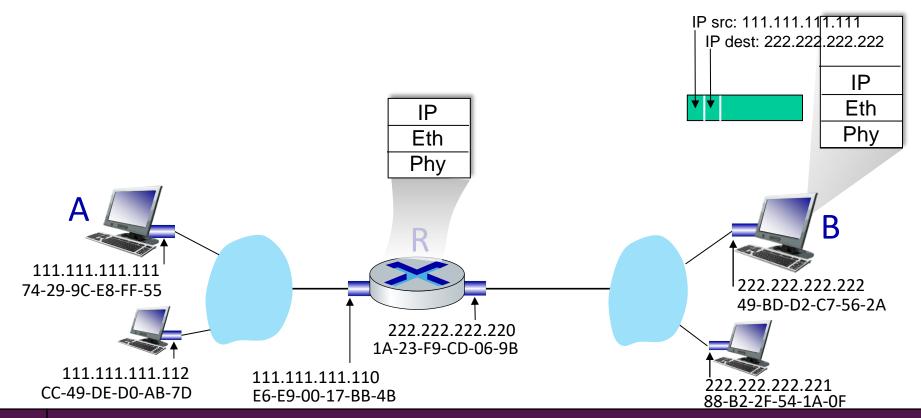

- R determines outgoing interface, passes datagram with IP source A, destination B to link layer
- R creates link-layer frame containing A-to-B IP datagram. Frame destination address: B's MAC address

- R determines outgoing interface, passes datagram with IP source A, destination B to link layer
- R creates link-layer frame containing A-to-B IP datagram. Frame destination address: B's MAC address

- B receives frame, extracts IP datagram destination B
- B passes datagram up protocol stack to IP

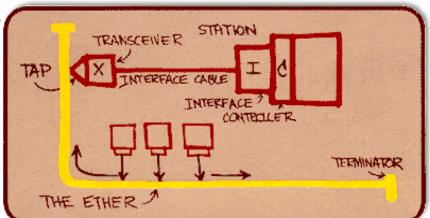

### **Ethernet**

### "dominant" wired LAN technology:

- first widely used LAN technology
- simpler, cheap
- kept up with speed race: 10 Mbps 400 Gbps
- single chip, multiple speeds (e.g., Broadcom BCM5761)

*Metcalfe's Ethernet sketch* 

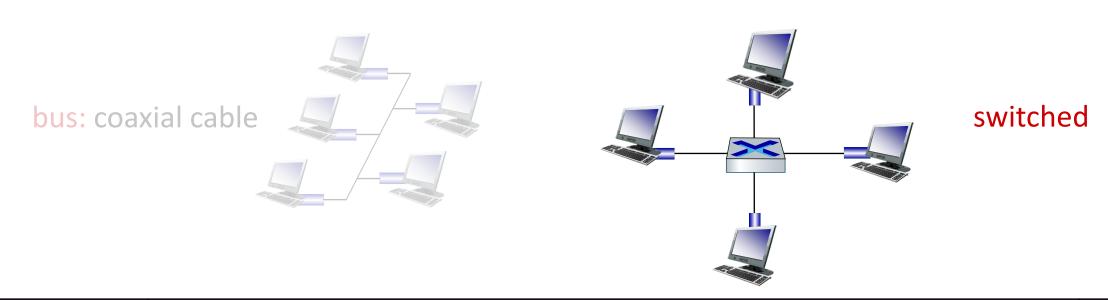

Bob Metcalfe: Ethernet co-inventor, 2022 ACM Turing Award recipient

https://www.uspto.gov/learning-and-resources/journeys-innovation/audio-stories/defying-doubters

# Ethernet: physical topology

- bus: popular through mid 90s
  - all nodes in same collision domain (can collide with each other)
- switched: prevails today
  - active link-layer 2 switch in center
  - each "spoke" runs a (separate) Ethernet protocol (nodes do not collide with each other)

### Ethernet frame structure

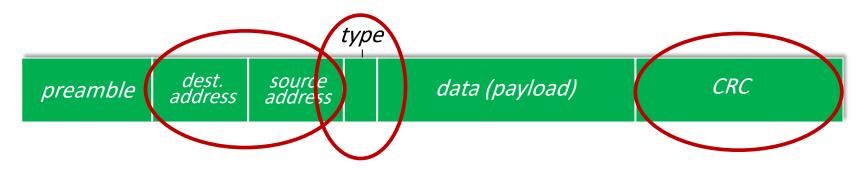

sending interface encapsulates IP datagram (or other network layer protocol packet) in Ethernet frame

#### preamble:

- used to synchronize receiver, sender clock rates
- 7 bytes of 10101010 followed by one byte of 10101011

## Ethernet frame structure (more)

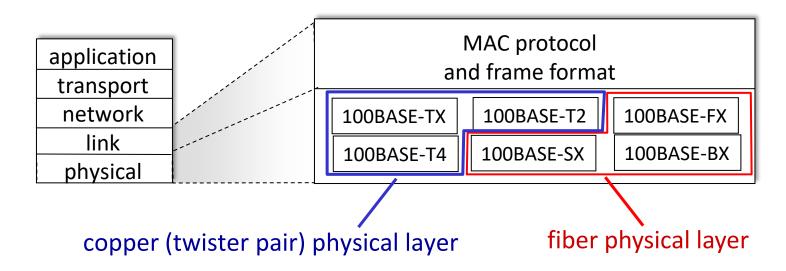

- addresses: 6 byte source, destination MAC addresses
  - if adapter receives frame with matching destination address, or with broadcast address (e.g., ARP packet), it passes data in frame to network layer protocol
  - otherwise, adapter discards frame
- type: indicates higher layer protocol
  - mostly IP but others possible, e.g., Novell IPX, AppleTalk
  - used to demultiplex up at receiver
- CRC: cyclic redundancy check at receiver
  - error detected: frame is dropped

# Ethernet: unreliable, connectionless

- connectionless: no handshaking between sending and receiving NICs
- •unreliable: receiving NIC doesn't send ACKs or NAKs to sending NIC
  - data in dropped frames recovered only if initial sender uses higher layer rdt (e.g., TCP), otherwise dropped data lost
- Ethernet's MAC protocol: unslotted CSMA/CD with binary backoff

## 802.3 Ethernet standards: link & physical layers

- many different Ethernet standards
  - common MAC protocol and frame format
  - different speeds: 2 Mbps, ... 100 Mbps, 1Gbps, 10 Gbps, 40 Gbps, 80 Gbps
    - different physical layer media: fiber, cable

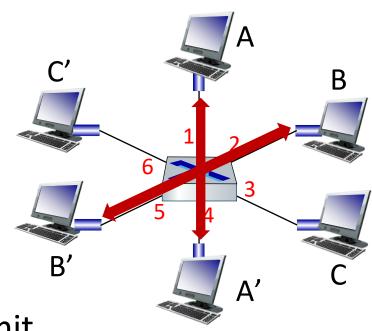

## **Ethernet switch**

- Switch is a link-layer device: takes an active role
  - store, forward Ethernet (or other type of) frames
  - examine incoming frame's MAC address, selectively forward frame to one-or-more outgoing links when frame is to be forwarded on segment, uses CSMA/CD to access segment
- transparent: hosts unaware of presence of switches
- plug-and-play, self-learning
  - switches do not need to be configured

# **Switch**

# Switch: multiple simultaneous transmissions

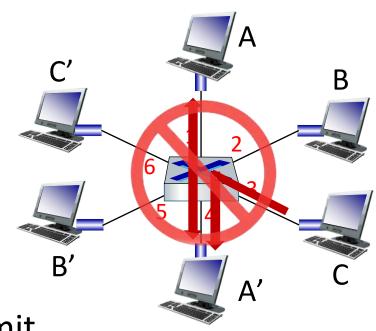

- hosts have dedicated, direct connection to switch
- switches buffer packets
- Ethernet protocol used on each incoming link, so:
  - no collisions; full duplex
  - each link is its own collision domain
- switching: A-to-A' and B-to-B' can transmit simultaneously, without collisions

switch with six interfaces (1,2,3,4,5,6)

# Switch: multiple simultaneous transmissions

- hosts have dedicated, direct connection to switch
- switches buffer packets
- Ethernet protocol used on each incoming link, so:
  - no collisions; full duplex
  - each link is its own collision domain
- switching: A-to-A' and B-to-B' can transmit simultaneously, without collisions
  - but A-to-A' and C to A' can not happen simultaneously

switch with six interfaces (1,2,3,4,5,6)

# Switch forwarding table

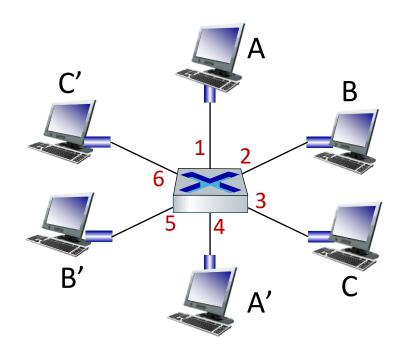

Q: how does switch know A' reachable via interface 4, B' reachable via interface 5?

<u>A:</u> each switch has a switch table, each entry:

- (MAC address of host, interface to reach host, time stamp)
- looks like a routing table!

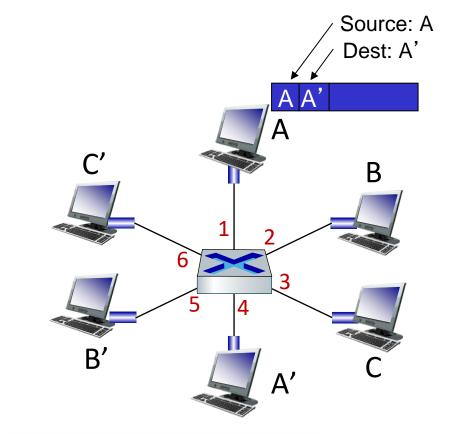

Q: how are entries created, maintained in switch table?

something like a routing protocol?

# Switch: self-learning

- switch *learns* which hosts can be reached through which interfaces
  - when frame received, switch "learns" location of sender: incoming LAN segment
  - records sender/location pair in switch table

MAC addr	interface	TTL
А	1	60

Switch table (initially empty)

# Switch: frame filtering/forwarding

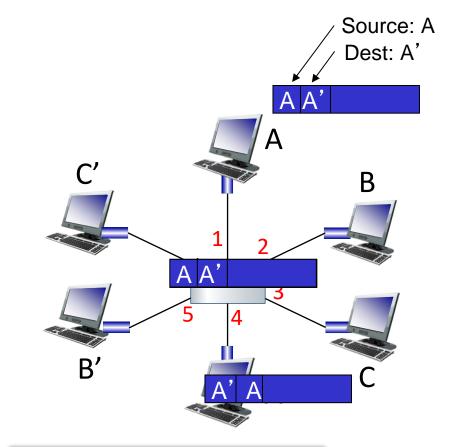

#### when frame received at switch:

- 1. record incoming link, MAC address of sending host
- 2. index switch table using MAC destination address

```
3. if entry found for destination
 then {
 if destination on segment from which frame arrived
     then drop frame
     else forward frame on interface indicated by entry
 }
 else flood /* forward on all interfaces except arriving interface */
```

# Self-learning, forwarding: example

- frame destination, A', location unknown: flood
- destination A location known: selectively send on just one link

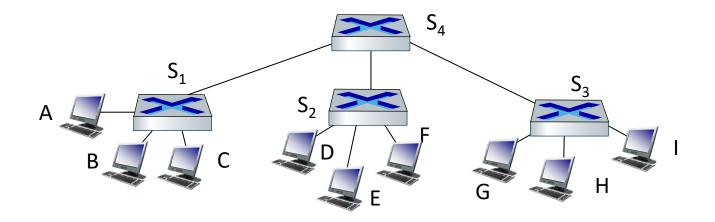

MAC addr	interface	TTL
Α Δ'	1	60 60
7	7	00

switch table (initially empty)

# Interconnecting switches

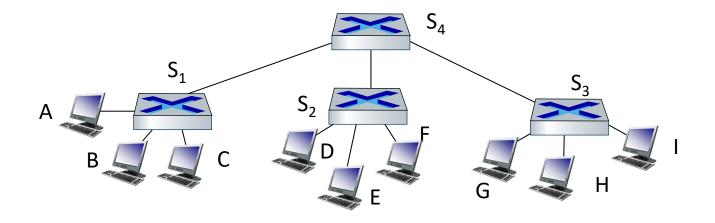

self-learning switches can be connected together:

- Q: sending from A to G how does S<sub>1</sub> know to forward frame destined to G via S<sub>4</sub> and S<sub>3</sub>?
- <u>A:</u> self learning! (works exactly the same as in single-switch case!)

# Self-learning multi-switch example

Suppose C sends frame to I, I responds to C

 $\underline{\mathbf{Q}}$ : show switch tables and packet forwarding in  $S_1$ ,  $S_2$ ,  $S_3$ ,  $S_4$ 

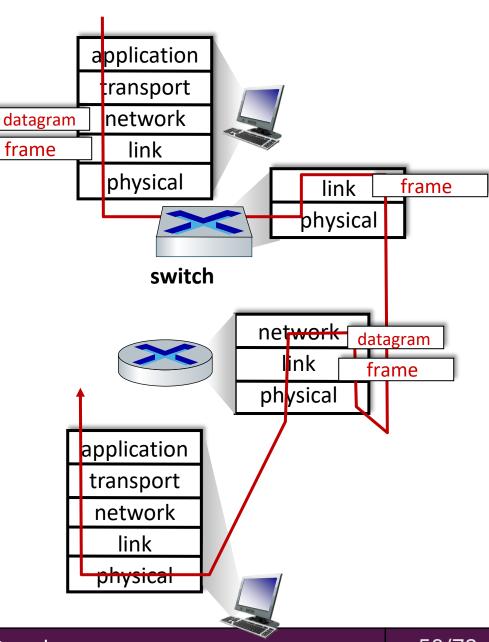

## Switches vs. routers

#### both are store-and-forward:

- routers: network-layer devices (examine network-layer headers)
- switches: link-layer devices (examine link-layer headers)

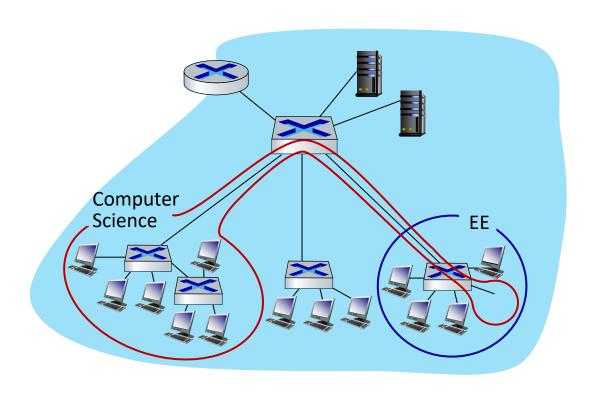

## both have forwarding tables:

- routers: compute tables using routing algorithms, IP addresses
- switches: learn forwarding table using flooding, learning, MAC addresses

# Virtual LANs (VLANs): motivation

Q: what happens as LAN sizes scale, users change point of attachment?

#### single broadcast domain:

- scaling: all layer-2 broadcast traffic (ARP, DHCP, unknown MAC) must cross entire LAN
- efficiency, security, privacy, efficiency issues

#### administrative issues:

 CS user moves office to EE - physically attached to EE switch, but wants to remain logically attached to CS switch

### Port-based VLANs

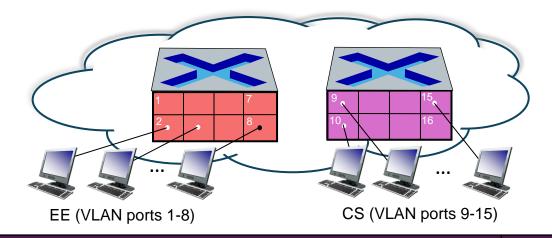

Virtual Local Area Network (VLAN)

switch(es) supporting VLAN capabilities can be configured to define multiple *virtual* LANS over single physical LAN infrastructure.

port-based VLAN: switch ports grouped (by switch management software) so that single physical switch .....

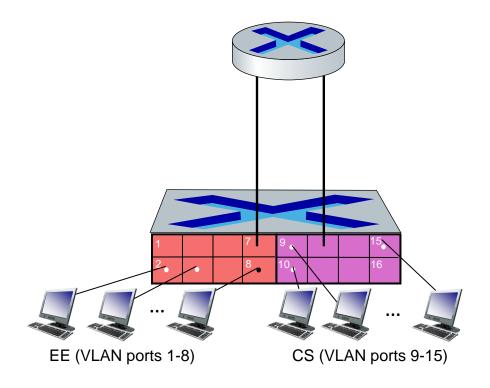

... operates as multiple virtual switches

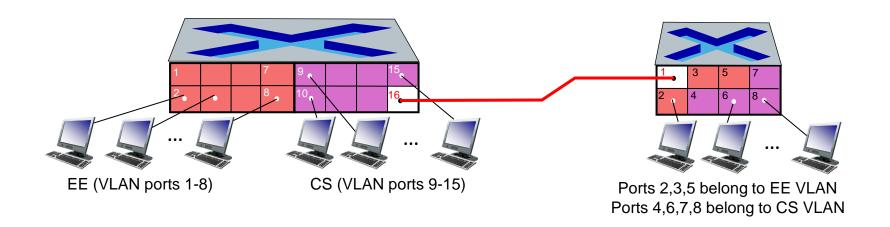

### Port-based VLANs

- traffic isolation: frames to/from ports
  1-8 can only reach ports
  - can also define VLAN based on MAC addresses of endpoints, rather than switch port
- dynamic membership: ports can be dynamically assigned among VLANs
- forwarding between VLANS: done via routing (just as with separate switches)
  - in practice vendors sell combined switches plus routers

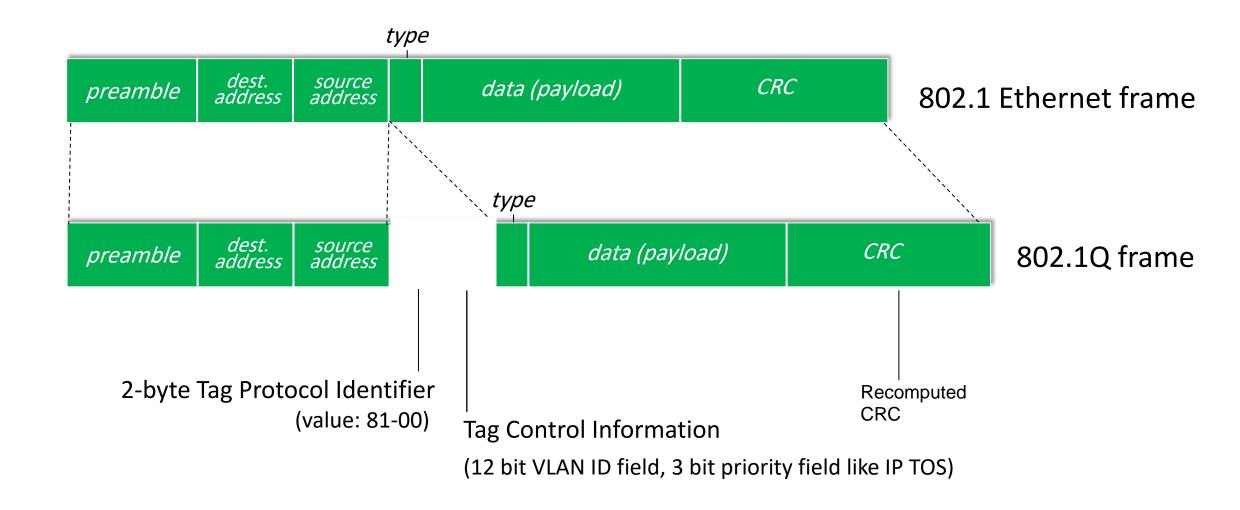

# VLANS spanning multiple switches

trunk port: carries frames between VLANS defined over multiple physical switches

- frames forwarded within VLAN between switches can't be vanilla 802.1 frames (must carry VLAN ID info)
- 802.1q protocol adds/removed additional header fields for frames forwarded between trunk ports

# 802.1Q VLAN frame format

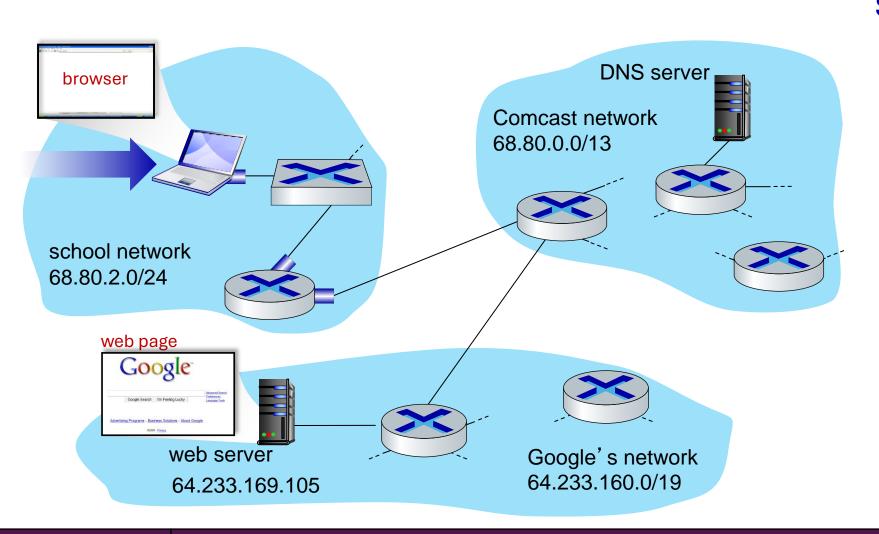

# A day in the life: scenario

# Synthesis: a day in the life of a web request

- our journey down the protocol stack is now complete!
  - application, transport, network, link
- putting-it-all-together: synthesis!
  - goal: identify, review, understand protocols (at all layers) involved in seemingly simple scenario: requesting www page
  - scenario: student attaches laptop to campus network, requests/receives www.google.com

# A day in the life: scenario

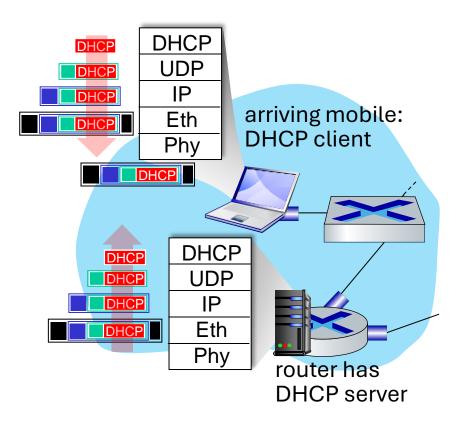

#### scenario:

- arriving mobile client attaches to network ...
- requests web page: www.google.com

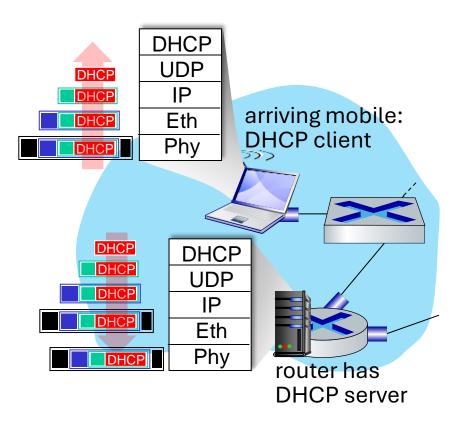

# A day in the life: connecting to the Internet

- connecting laptop needs to get its own IP address, addr of first-hop router, addr of DNS server: use DHCP
- DHCP request encapsulated in UDP, encapsulated in IP, encapsulated in 802.3 Ethernet
- Ethernet de-muxed to IP de-muxed, UDP de-muxed to DHCP

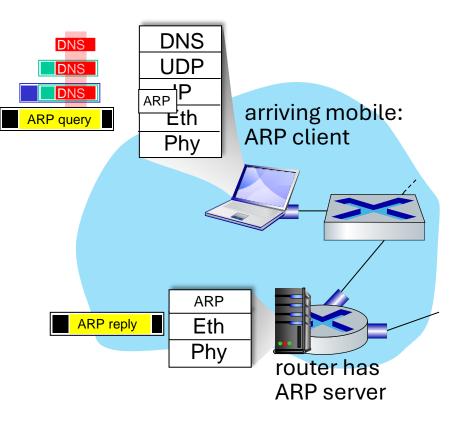

# A day in the life: connecting to the Internet

- DHCP server formulates DHCP ACK containing client's IP address, IP address of first-hop router for client, name & IP address of DNS server
- encapsulation at DHCP server, frame forwarded (switch learning) through LAN, demultiplexing at client
- DHCP client receives DHCP ACK reply

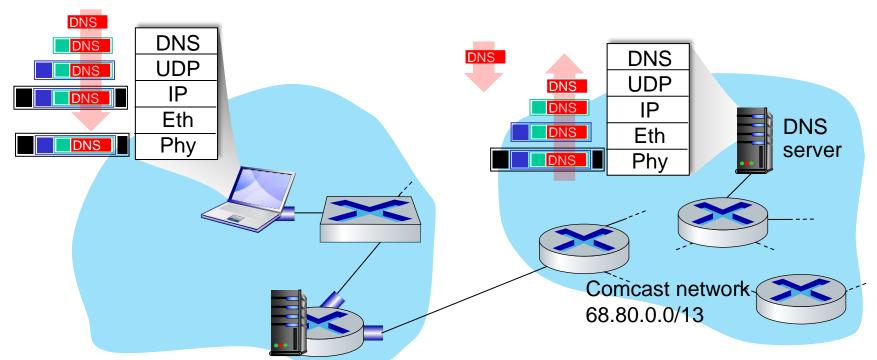

Client now has IP address, knows name & addr of DNS server, IP address of its first-hop router

# A day in the life... ARP (before DNS, before HTTP)

- before sending HTTP request, need IP address of www.google.com: DNS
- DNS query created, encapsulated in UDP, encapsulated in IP, encapsulated in Eth. To send frame to router, need MAC address of router interface: ARP
- ARP query broadcast, received by router, which replies with ARP reply giving MAC address of router interface
- client now knows MAC address of first hop router, so can now send frame containing DNS query

# A day in the life... using DNS

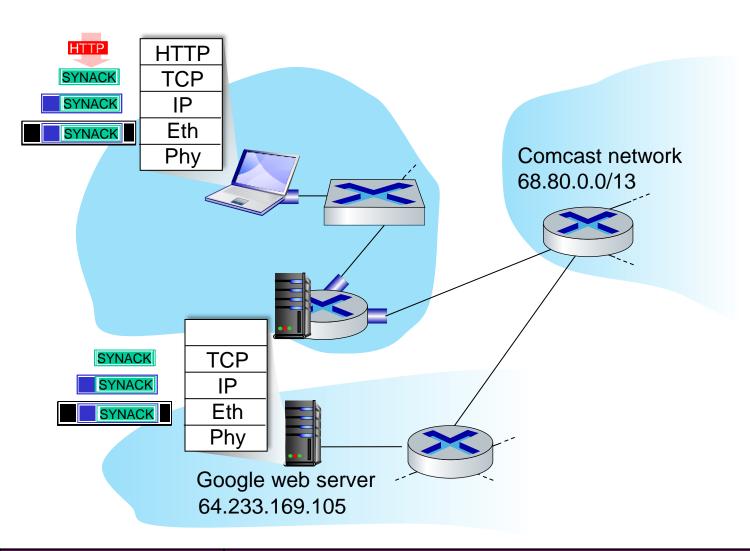

- de-muxed to DNS
- DNS replies to client with IP address of www.google.com

 IP datagram containing DNS query forwarded via LAN switch from client to 1<sup>st</sup> hop router

 IP datagram forwarded from campus network into Comcast network, routed (tables created by RIP, OSPF, IS-IS and/or BGP routing protocols) to DNS server

# A day in the life...TCP connection carrying HTTP

- to send HTTP request, client first opens TCP socket to web server
- TCP SYN segment (step 1 in TCP 3-way handshake) interdomain routed to web
- Webserver responds with TCP SYNACK (step 2 in TCP 3-way handshake)
- TCP connection established!

# A day in the life... HTTP request/reply

- HTTP request sent into TCP socket
- IP datagram containing HTTP request routed to www.google.com
- web server responds with HTTP reply (containing web page)
- IP datagram containing HTTP reply routed back to client
